

# Tony Creek Dual Microseismic Experiment (ToC2ME)

Nadine Igonin

Andrew Poulin

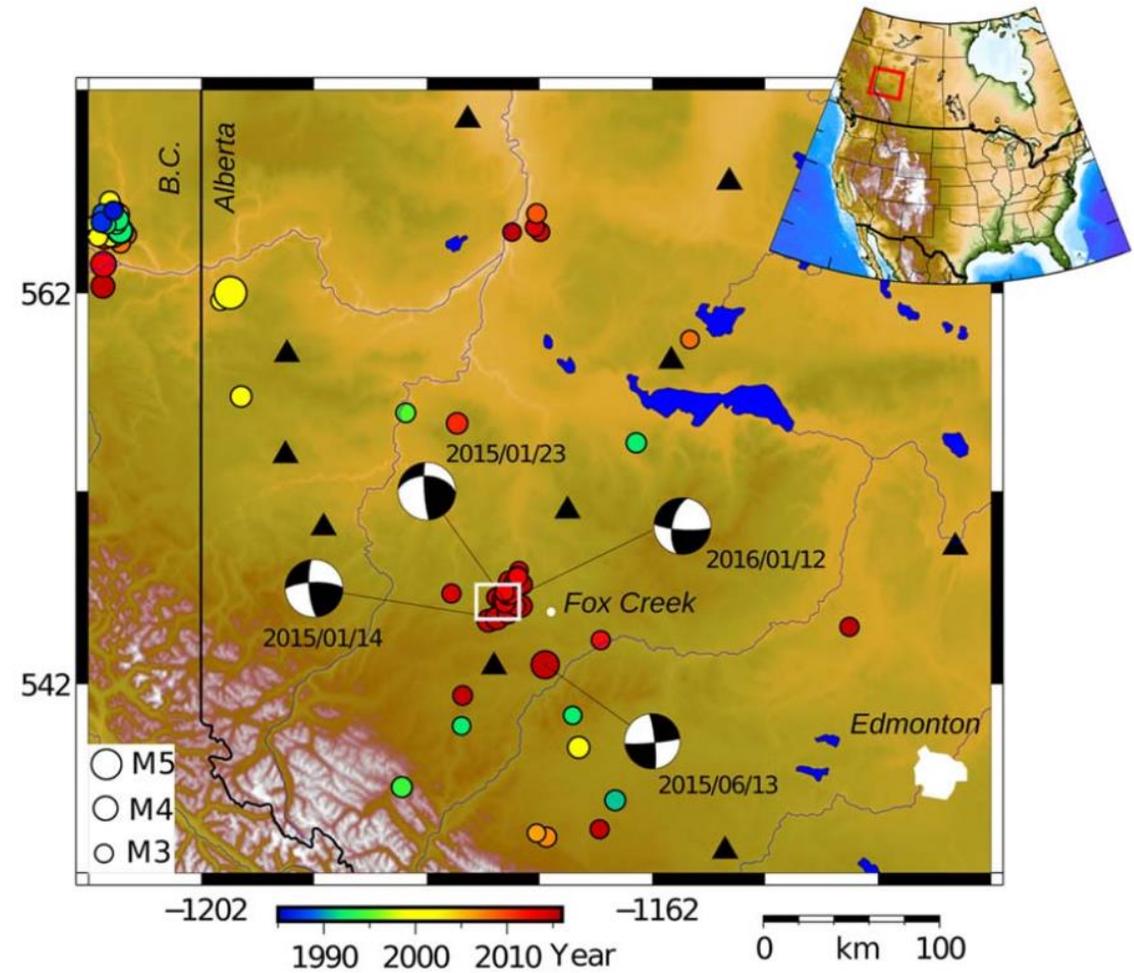

David Eaton

# Outline

- Background
- Field experiment
- Data
- Preliminary results
- Future work

# Background

- **Induced seismicity** in Alberta
- Caused mainly by hydraulic fracturing
- In the Fox Creek area, the target is the Duvernay, approximately 3.5 km deep
- Earthquakes as large as ML 4.6 have been triggered

Bao & Eaton, 2016

# Background: Monitoring

Monitoring falls into two categories:

## 1. Microseismic monitoring

- $M < 0$
- Many *nearby* stations (dx: 50 – 500 m)
- Surface or downhole monitoring
- 15 Hz geophones

## 2. Induced seismicity monitoring

- $M > 0$
- Many *sparse* stations (dx: 2 km – 100 km)
- Dominantly surface monitoring
- Broadband seismometers  
( $f \leq 0.01$  Hz)

# Field Experiment

## Field site:

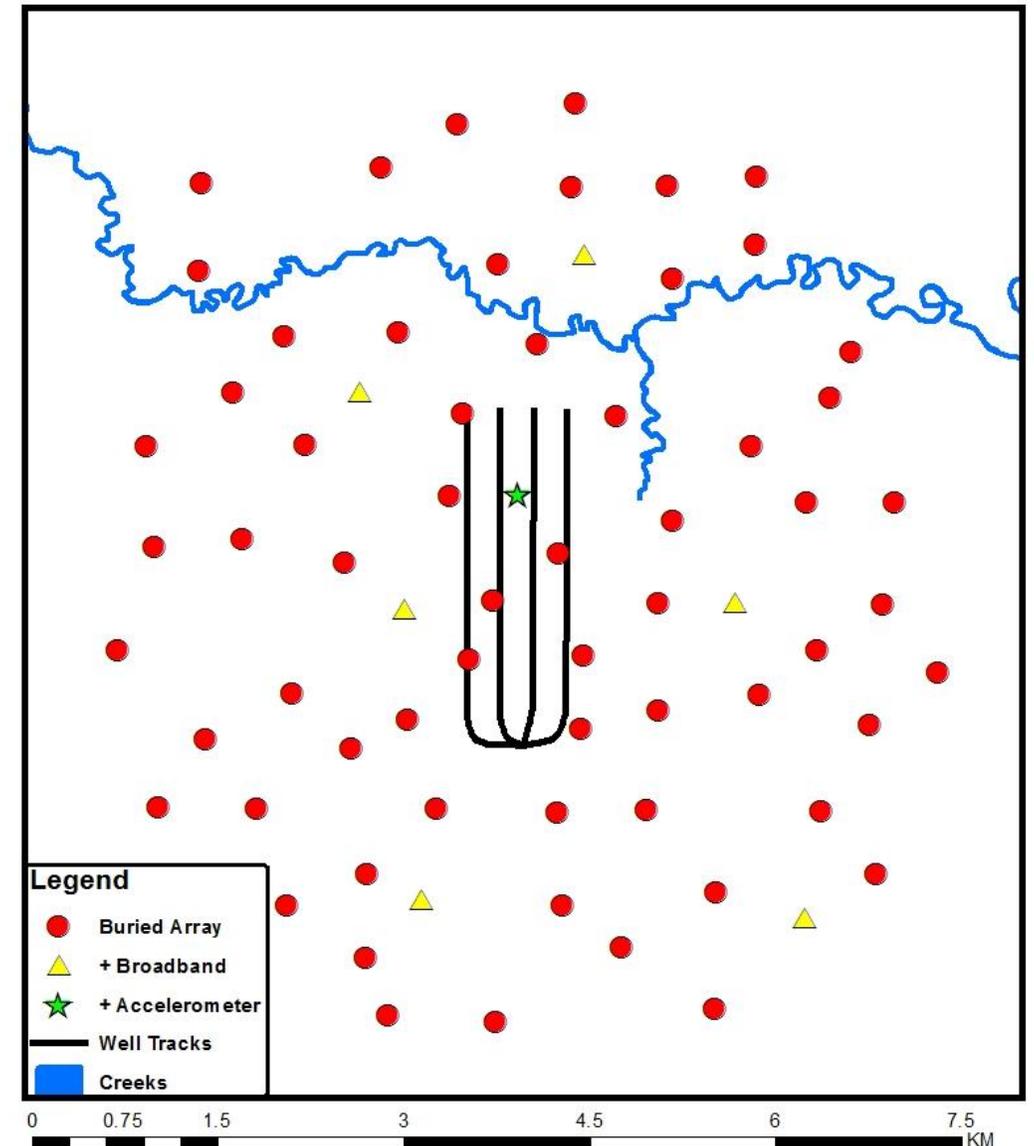

- West of Fox Creek
- 56 km<sup>2</sup> area
- 4 wells – 2.5 km each

## Equipment:

- 69-station shallow borehole array
- 6 broadband seismometers
- 1 accelerometer
- (+ a few surface 3C geophones)

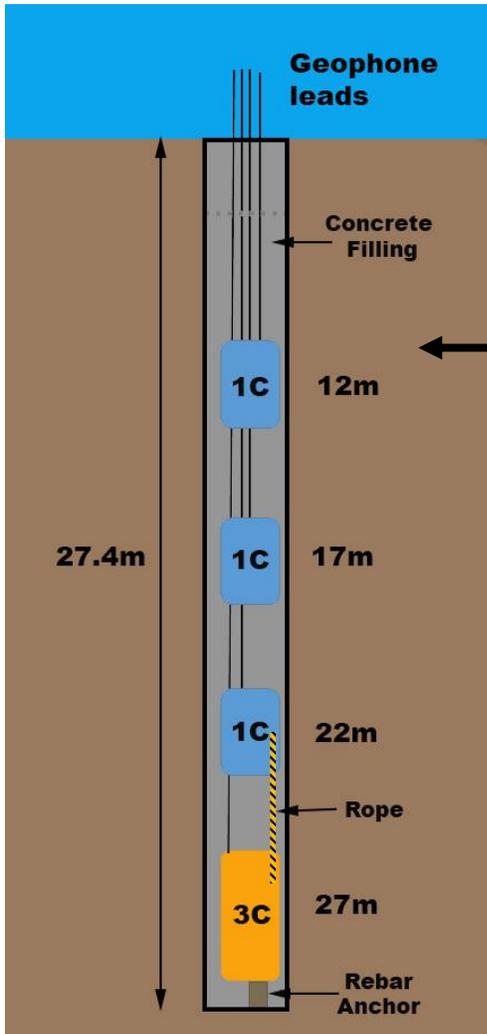

## Timeline:

- Mid-October to early December 2016

# Field Experiment

Shallow borehole array

Broadband seismometer

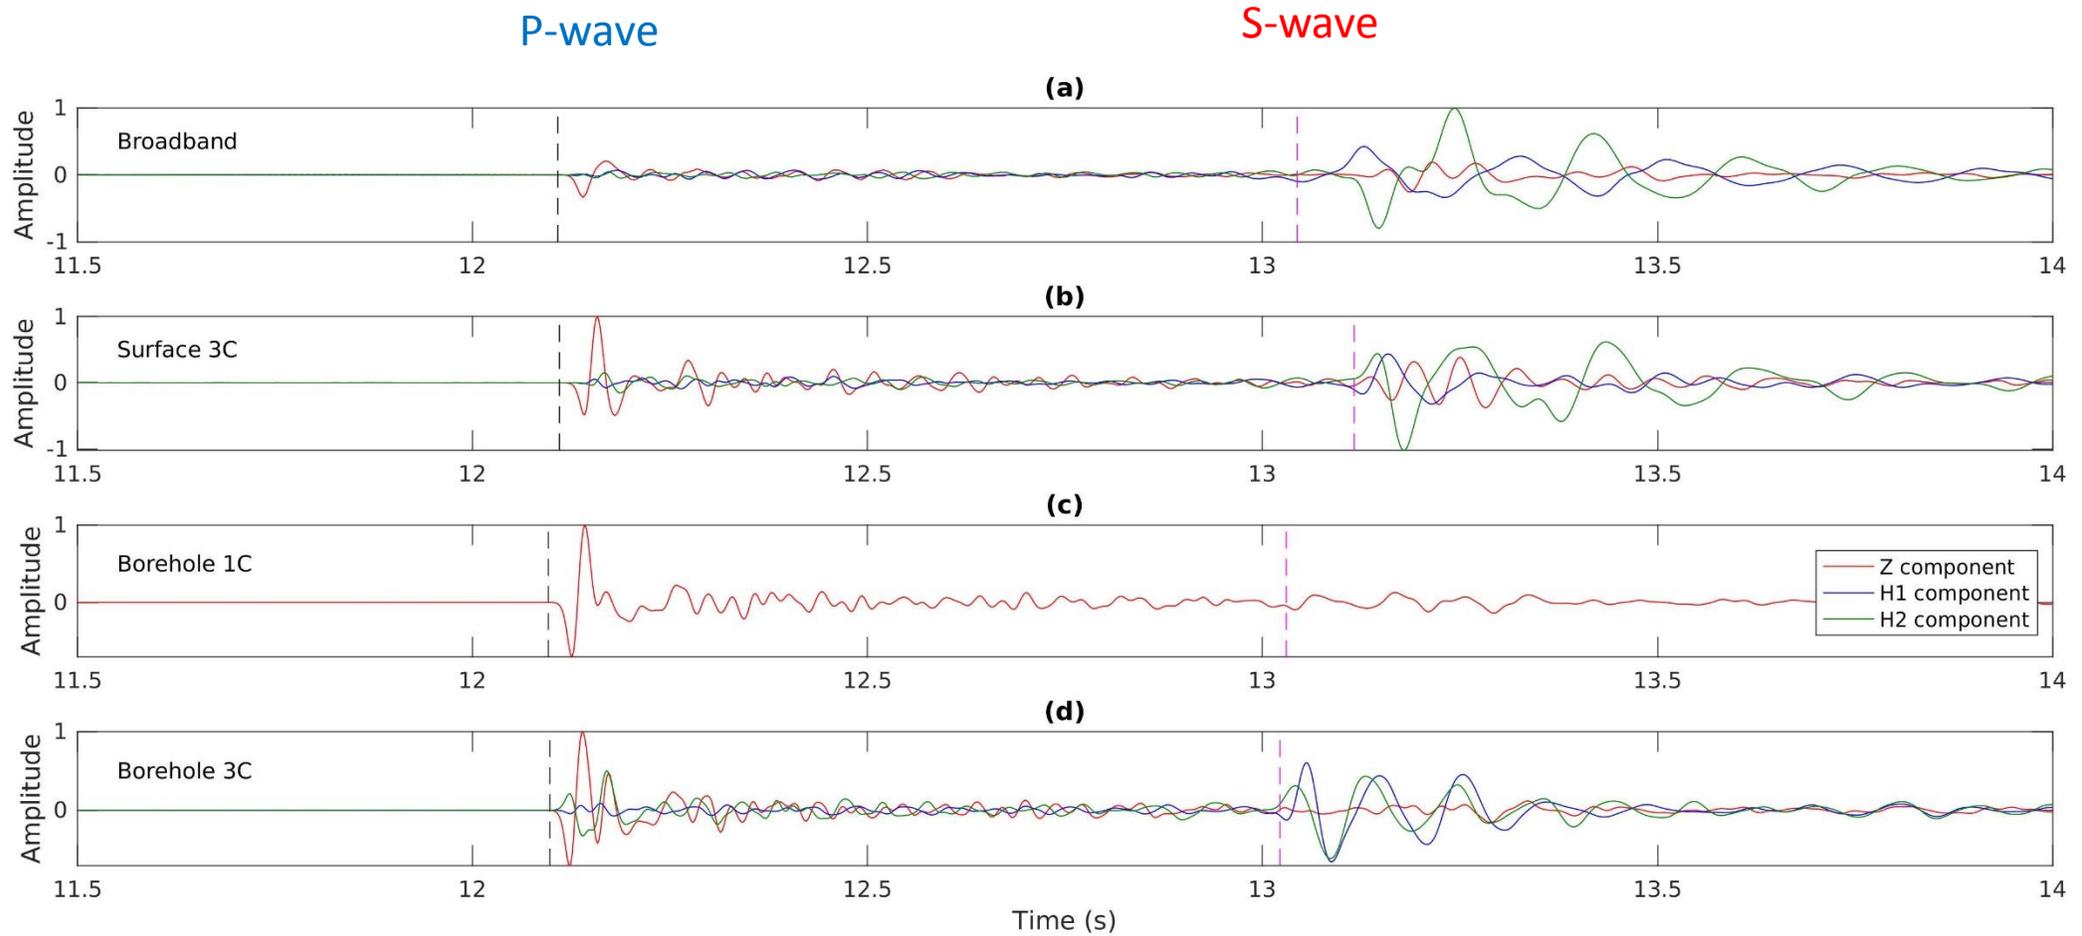

Surface 3C geophone

- We have:
  - 50 days of continuous data from the shallow borehole array (.sg2)
  - 65 days of continuous data from the broadband/accelerometer
- In total: 4TB of data
- Recorded 9 events above ML 3.0 – a record for this region

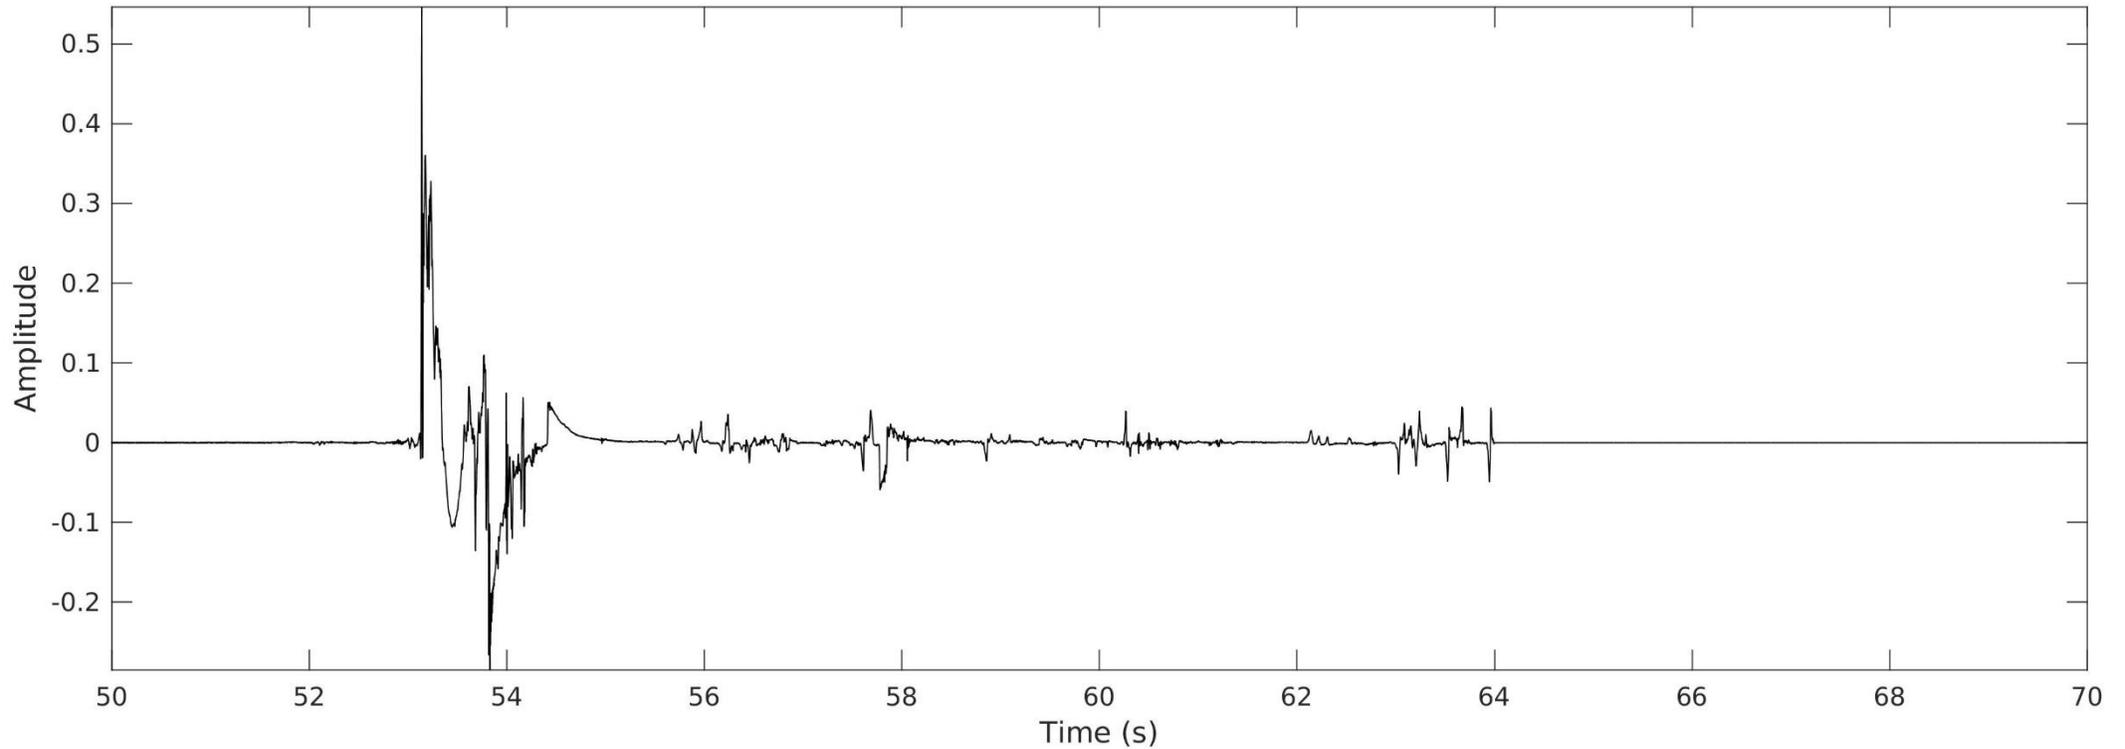

# Preliminary Results: Microseismic Events

- Example Mw 1.6 event:

Phase shifts between broadband and geophones

# Preliminary Results: "Unidentified waveform"

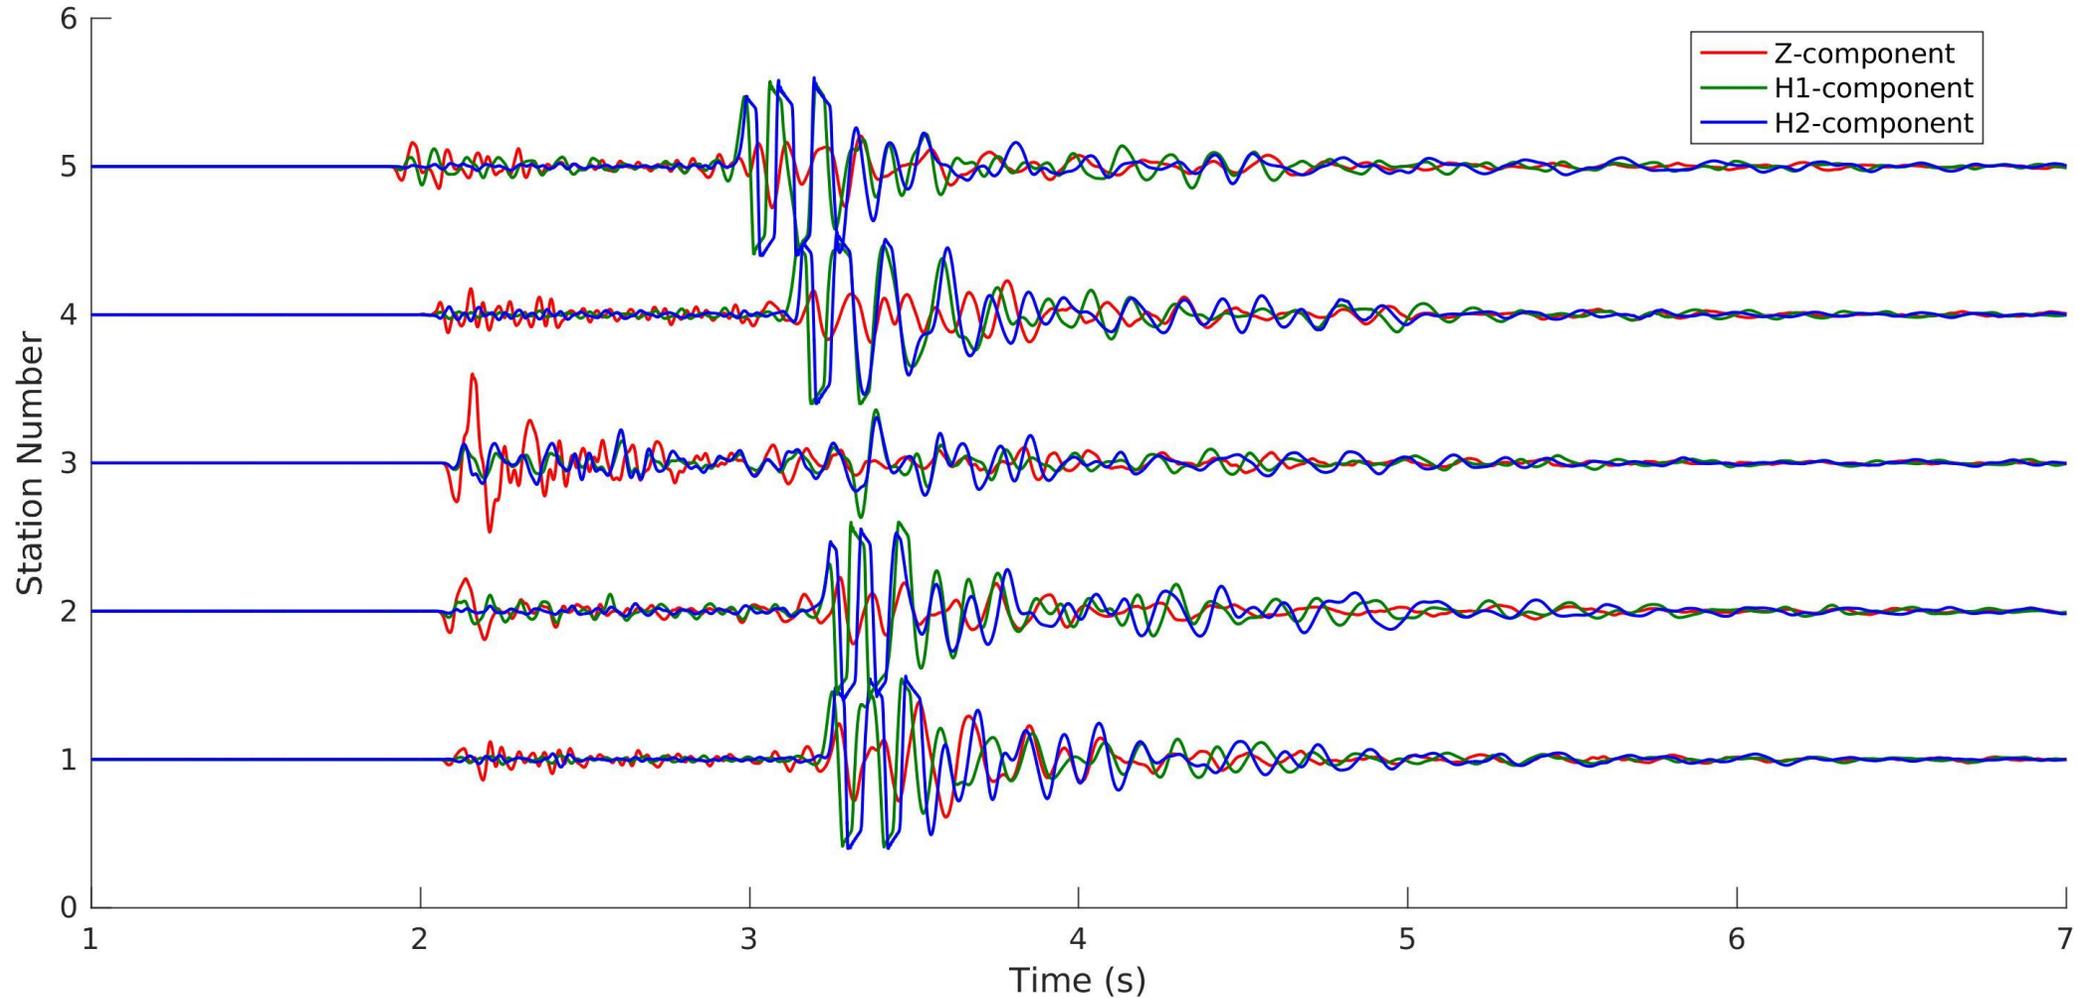

# Preliminary Results: "Unidentified waveform"

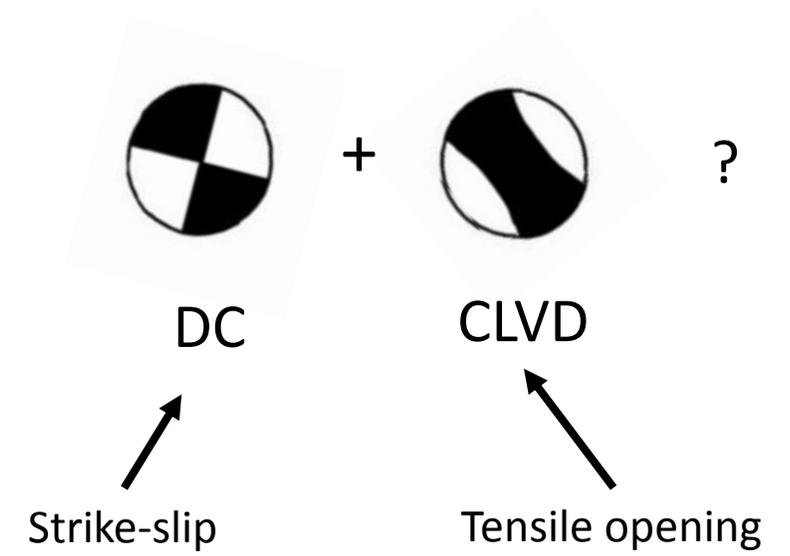

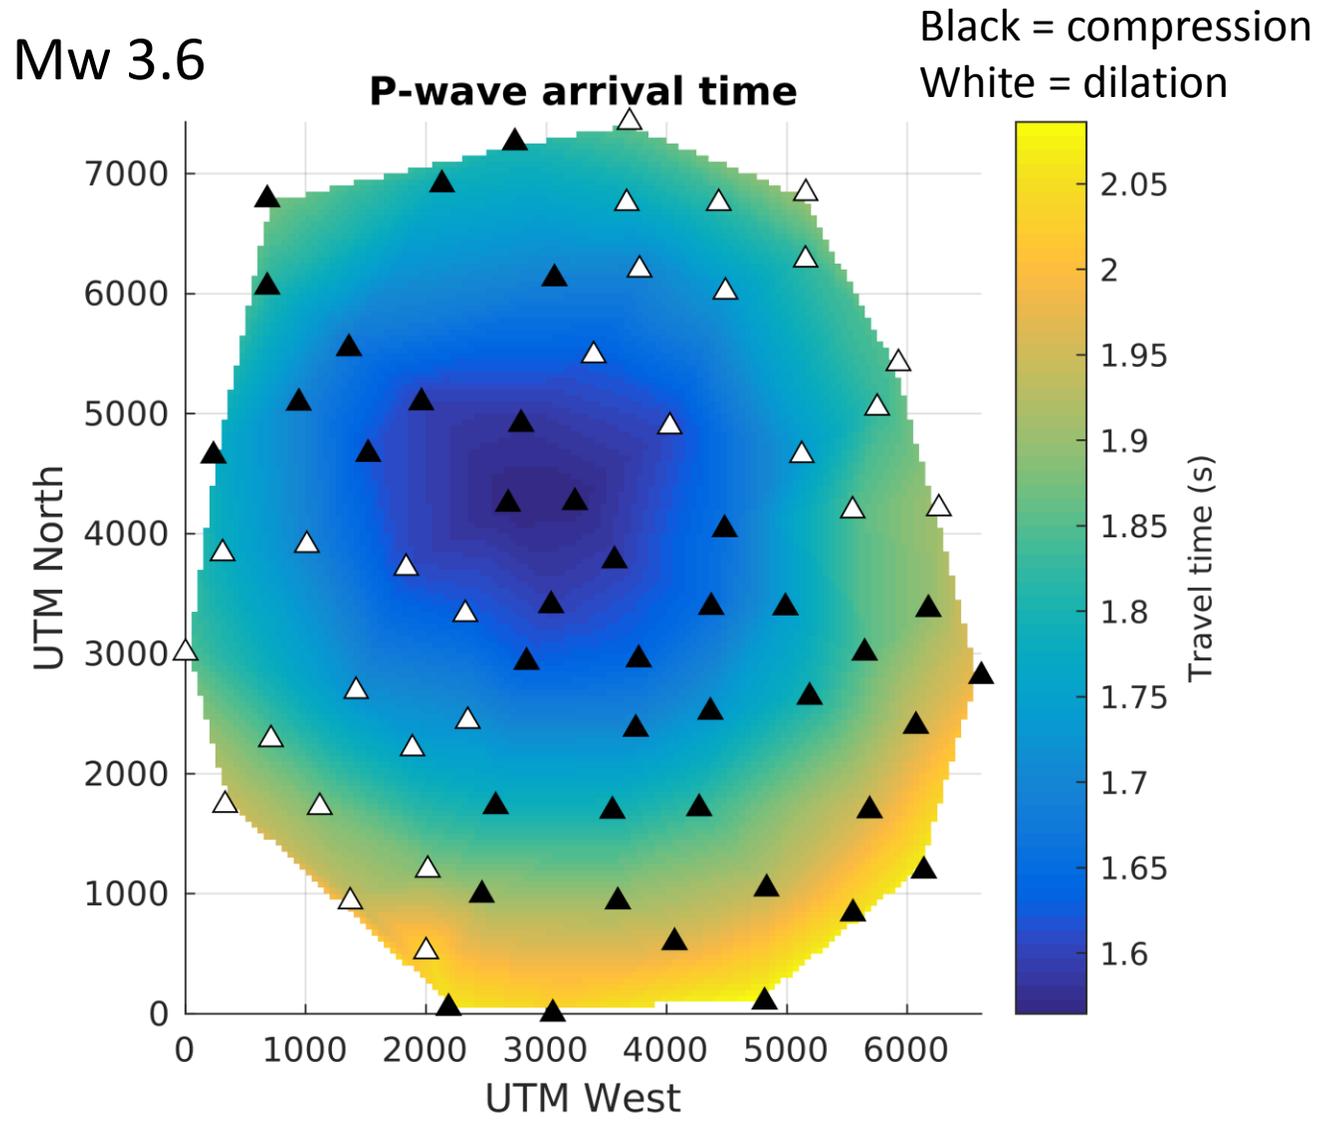

⇒ Moose attack on station

# Preliminary Results: Clipped Event

- Mw 3.6

# Preliminary Results: "Focal Mechanism"

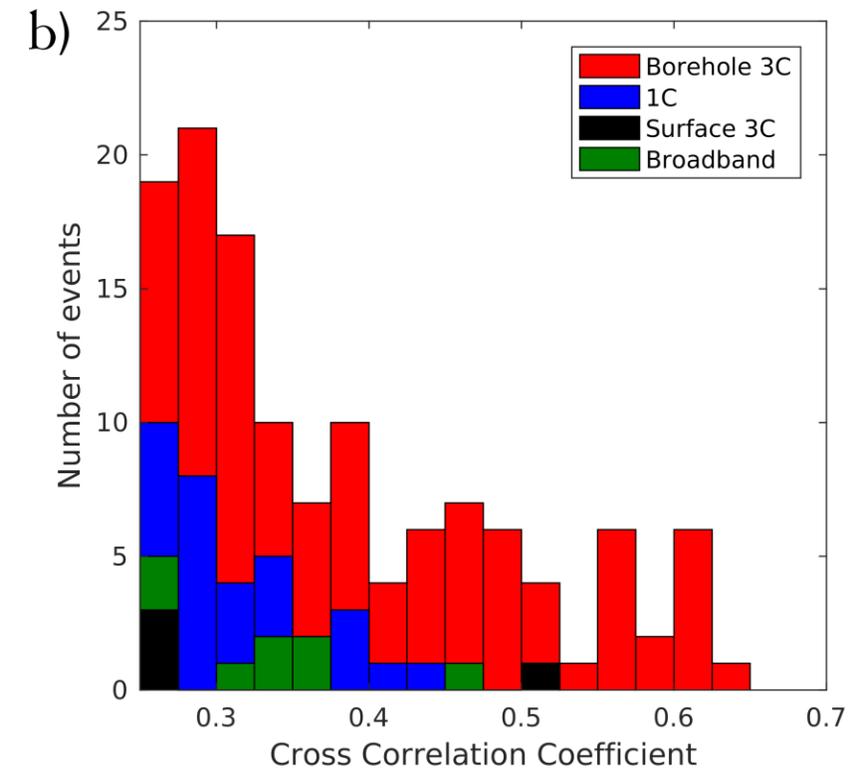

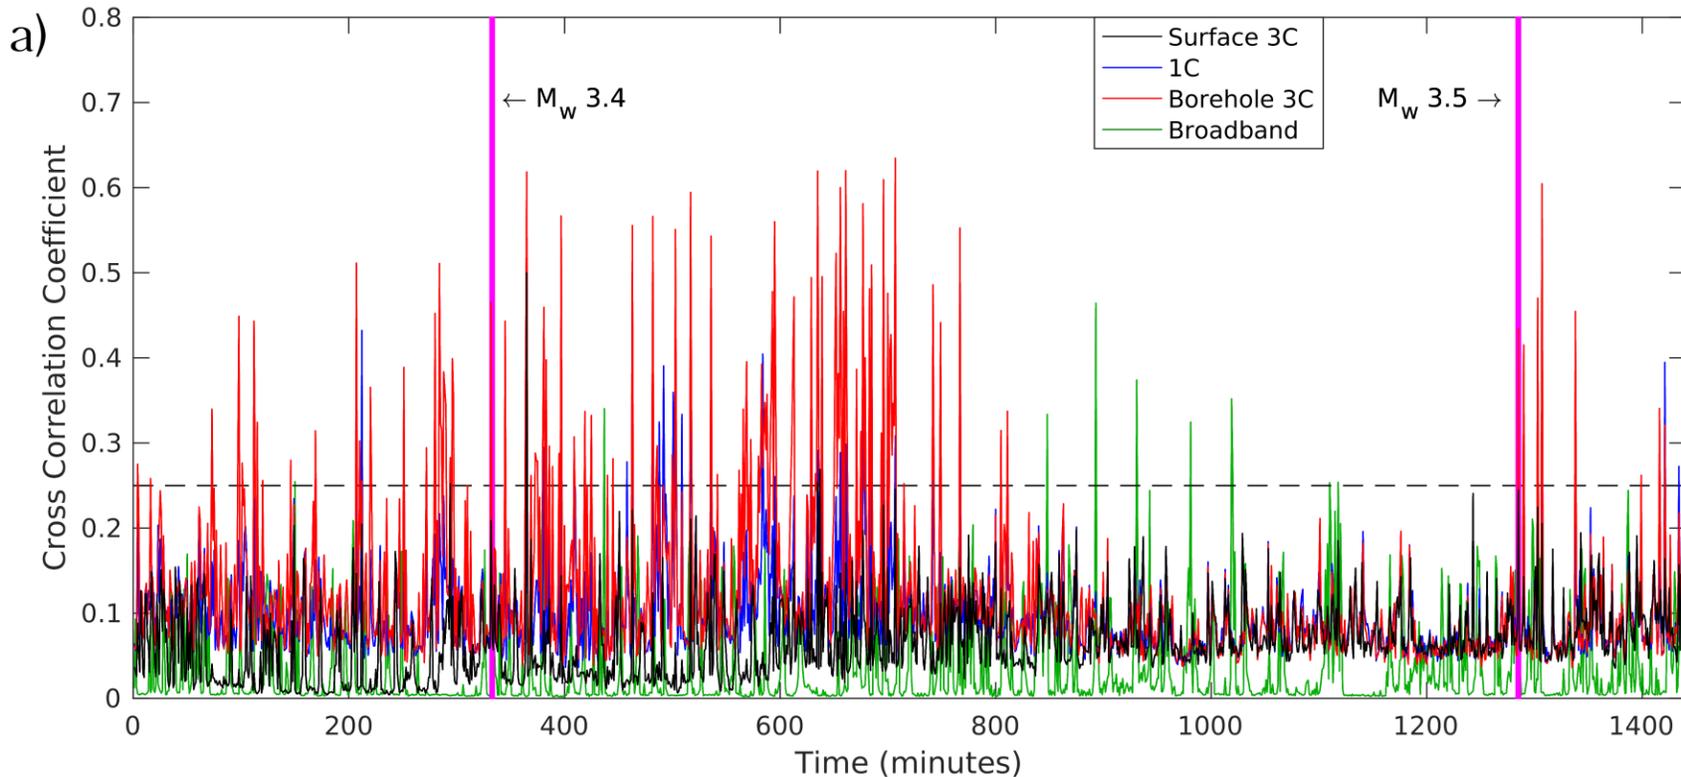

# Preliminary Results: Cross Correlation i.e. MFA

- **MFA** = Matched Filtering Analysis
  - MFA is a **template-based** approach of detecting microseismic events in raw data using the waveforms of select template events and **cross correlation**.
- Some terminology:
  - '**Parent**' – original template ; '**child**' – event found using parent

# Preliminary Results: Cross Correlation

⇒ Verdict: The **borehole 3C** is the best for event detection during noisy periods, but the **broadband** does better in quieter conditions

# Future work

- Microseismic processing (locations, magnitudes etc.)
  - Developing an approach using Full Waveform Inversion (FWI) to simultaneously converge upon source parameters and a velocity model.
    - Joint work between the MIC and the CREWES.
  - Geomodelling
    - Combining well log data and 3C/3D seismic data to build a geomodel for the area.
- + other exciting, unexpected directions!

# Conclusions

- The Tony Creek Dual Microseismic Experiment (ToC2ME ) was presented
- Induced seismicity **and** microseismic monitoring systems
- Preliminary results show this is a rich and very interesting dataset
- A lot of future work!

# Acknowledgements

We would like to thank:

- Terra Sine and Nanometrics for their tremendous help with the field work
- The anonymous companies for letting us monitor their hydraulic fracturing treatment
- The sponsors of the Microseismic Industry Consortium
- Natural Sciences and Engineering Research Council of Canada (NSERC)

Thank you!
